PCF Table Dropdown

Description

SingleSelectDropdown control **"converts"** a text field into a dropdown populated from values stored in a Dataverse table.

Simply select a source table and the field whose value should be stored in the text field. Optionally, you can specify a description field to provide additional context and a filter to limit the available options.

Common scenarios

- A field was originally created as text but later needs to be extended with a dropdown (e.g. adding a country dropdown to the standard **Country/Region** field on **Account** to simplify user input).
- You want Choice-like functionality where available values can be managed through a Dataverse table/App.
- You want a lookup-like experience without being tied to an actual relationship (e.g. referring to a table with temporary data that is constantly recreated).
- You want to build a Business Rule with a condition based on a lookup value without being tied to a specific GUID.

Notes

This control is intended to simulate a Choice field. Therefore:

- It is not intended for very large lists and does not support pagination.
- It does not provide lookup-style search. However, values are sorted alphabetically, and typing automatically jumps to the first matching value.

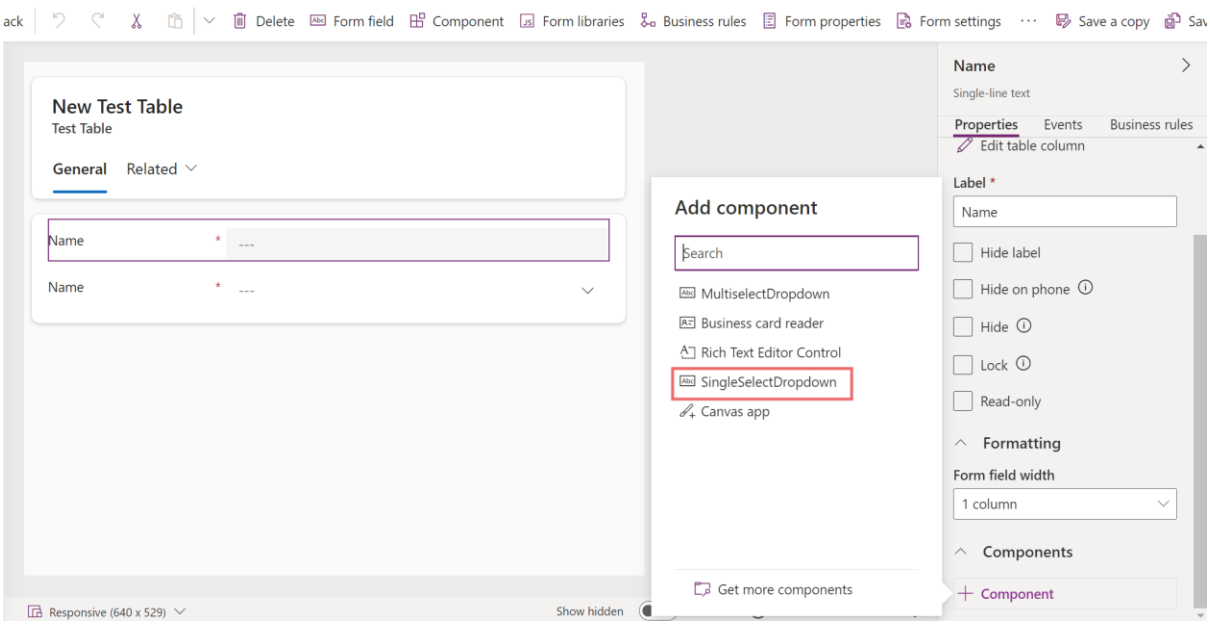

Installation

Simply import a solution to your Dataverse environment.

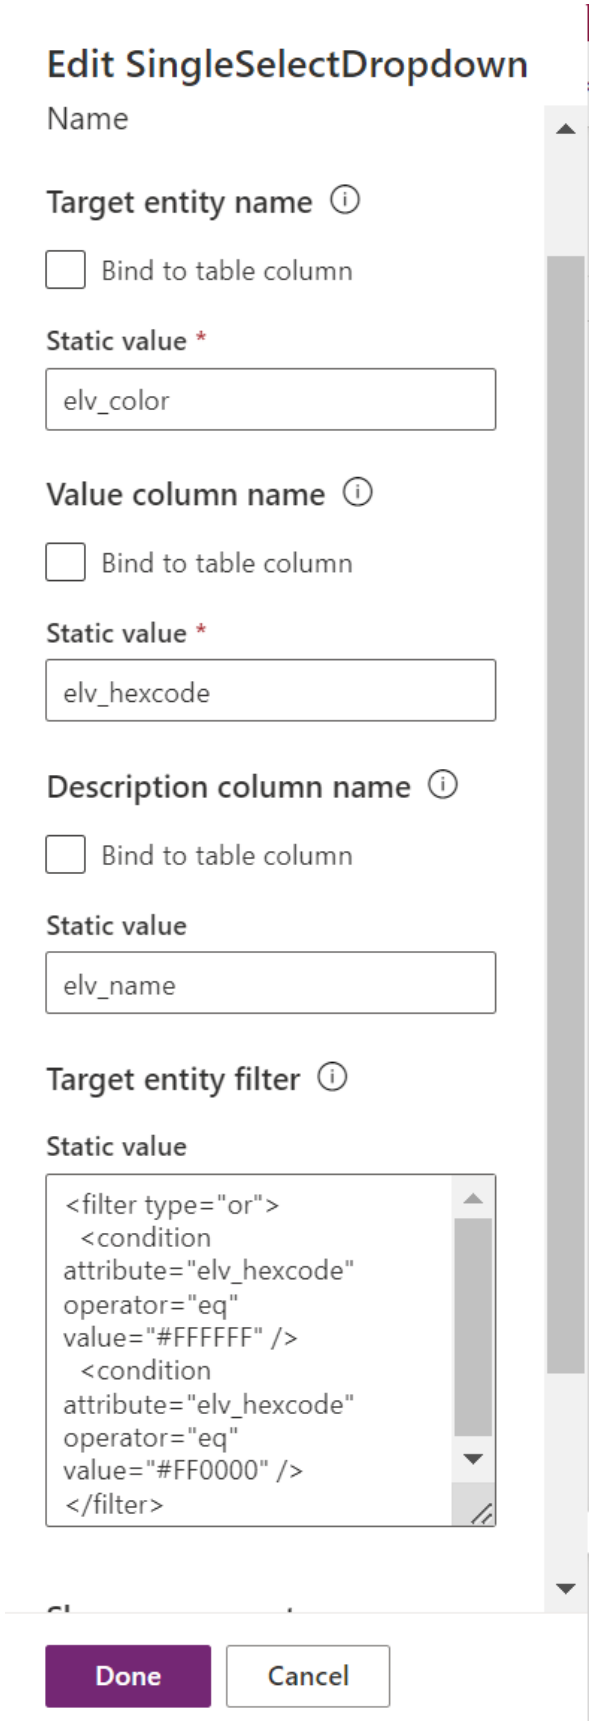

How to use

1) Open a form with a chosen Single Line of Text field.
2) Select a field.

3) In right pane click **Component** -> **+Component** -> **SingleSelectDropdown.**

4) In the configuration screen:
   a. Target entity name – logical name of the source table.
   b. Value column name – logical name of the column to be displayed and saved.
   c. Description column name – logical name of additional optional column to be displayed to bring more context to the value.
   d. Target entity filter – FetchXML filter for a source table.
      Note: you need to put only the filter itself from *<filter>* to *</filter>*.

5) Click **Done**.
6) **Save and Publish** the form.
